Eliot Quataert

Chung-Pei Ma

# How important are gas-poor mergers for building massive elliptical galaxies?

- Expected in current galaxy formation models embedded in LCDM simulations
- Help explain dichotomy between bright and faint ellipticals
- Have been observed
- Tension with evolution of galaxy luminosity functions?
- Consistency with tight observed scaling relations?

# Merger Simulations

- Model elliptical galaxy as Hernquist stellar bulge + NFW dark matter halo w/ and w/o adiabatic contraction) - no black holes, no gas  
*important:  $\Delta E_p \neq 0$*
- Simulate mass ratios of 1:1, 1:3
- Use distribution of orbits seen in cosmological dark matter simulations
- over  $10^6$  particles per simulation;  
run using GADGET

# Fundamental Plane

Virial Theorem:

$$R \propto \sigma^{-2} M_{\text{dyn}}$$

$$R \propto \sigma^{-2} (M_{\text{dyn}}/L) L$$

# Fundamental Plane

**K-band FP:**

$$R_e \propto \sigma^{1.53 \pm 0.08} I_e^{-0.79 \pm 0.03}$$

(Pahre et al. 1998)

$$M_{\text{dyn}}/L \propto R_e^{0.21}$$

Tilt due to increasing dark matter fraction in with increasing  $R_e$

See also Capelato et al. 1995, Nipoti et al. 2003, Robertson et al. 2006

# $M_{\text{p}}$ - $\sigma$ and $R_e$ - $M_{\text{p}}$ relations

MBK, Ma, & Quataert (MNRAS, 2006)

Angular momentum  $\rightarrow$

$\alpha$

Full elliptical galaxy population:

$$L \propto \sigma^4$$

$$R_e \propto L^{0.6-0.7}$$

# Brightest Cluster Galaxies

- Clusters form at intersections of filaments  $\Rightarrow$  natural preferred direction for merging

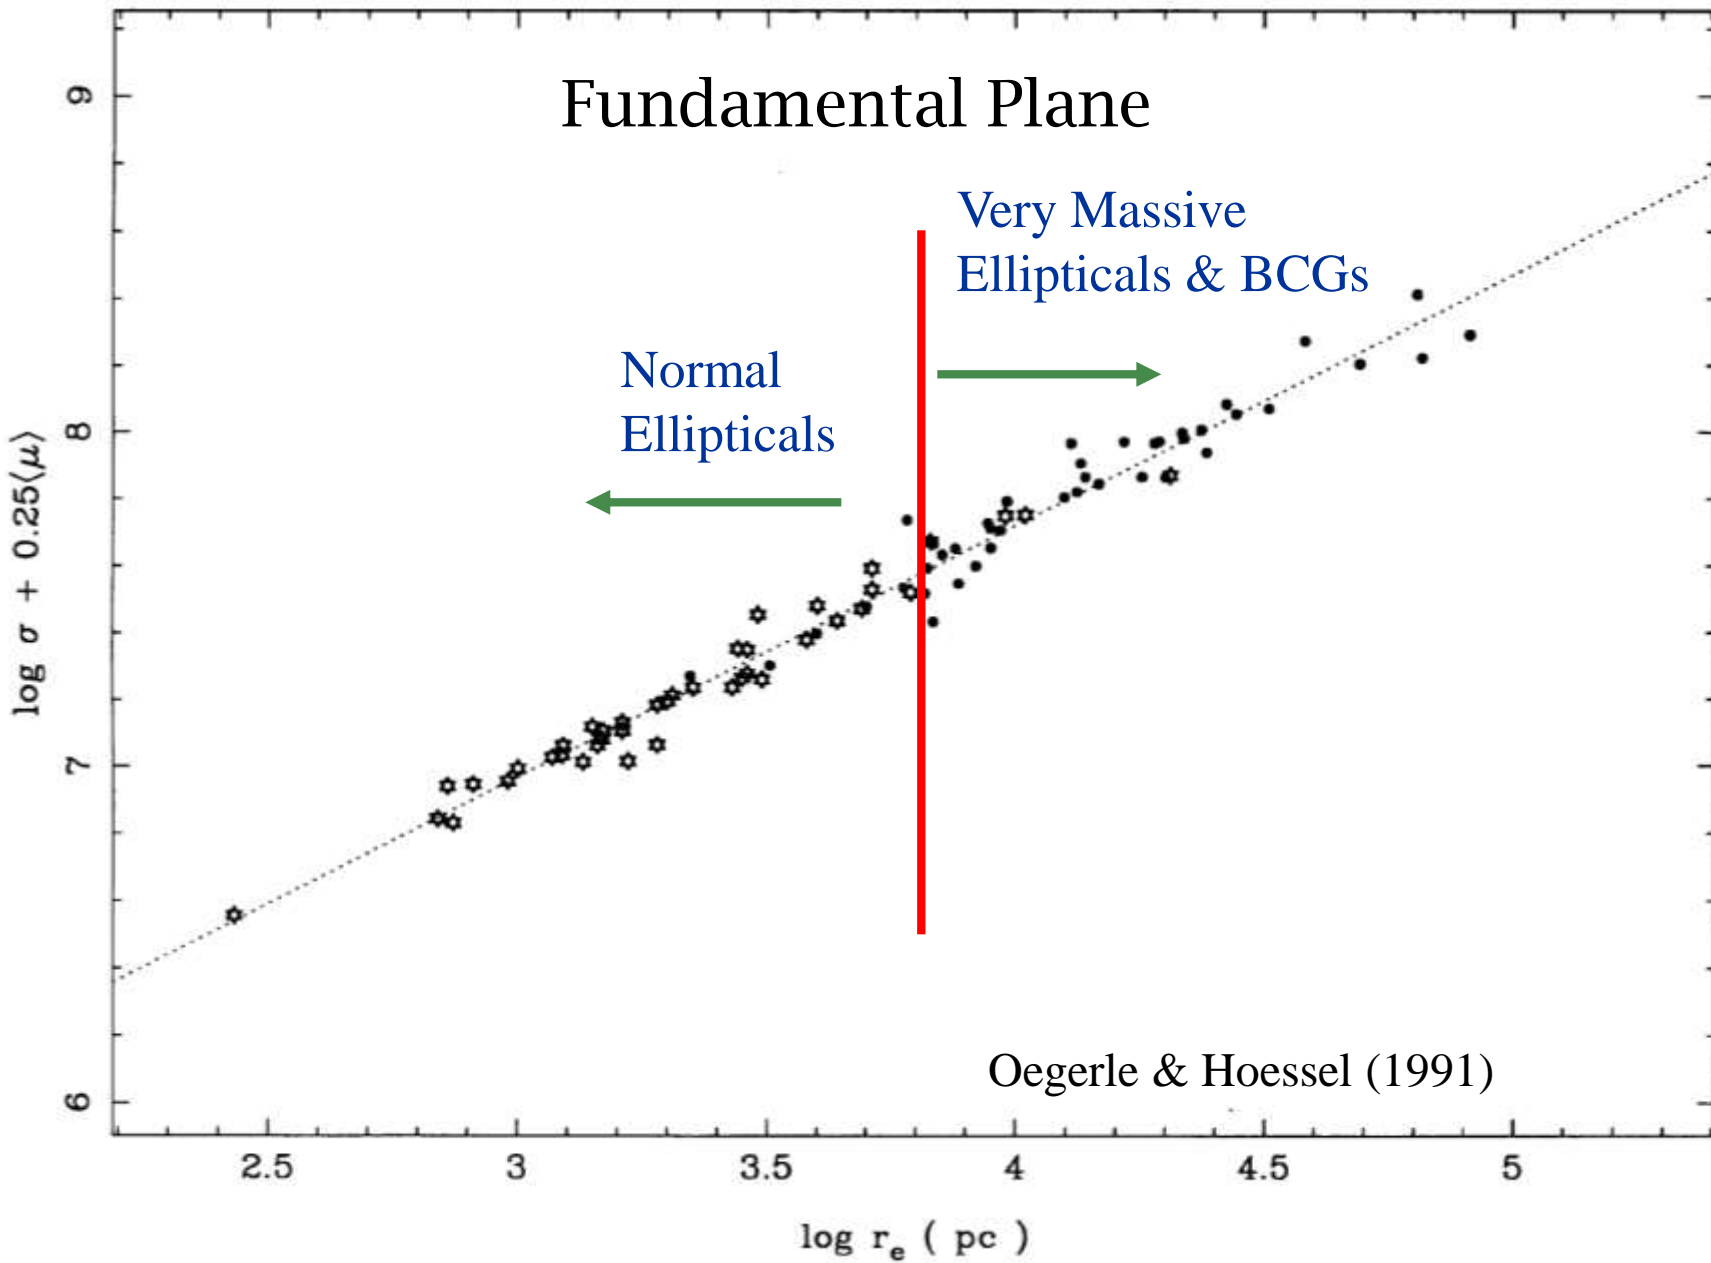

$\Rightarrow$  If BCGs are assembled by dissipationless mergers during cluster formation, orbits should be preferentially radial.

$\Rightarrow$  This radial merging will preserve the fundamental plane but lead to deviations in  $M_p \propto \sigma^\beta$  and  $R \propto M_p^\alpha$ :

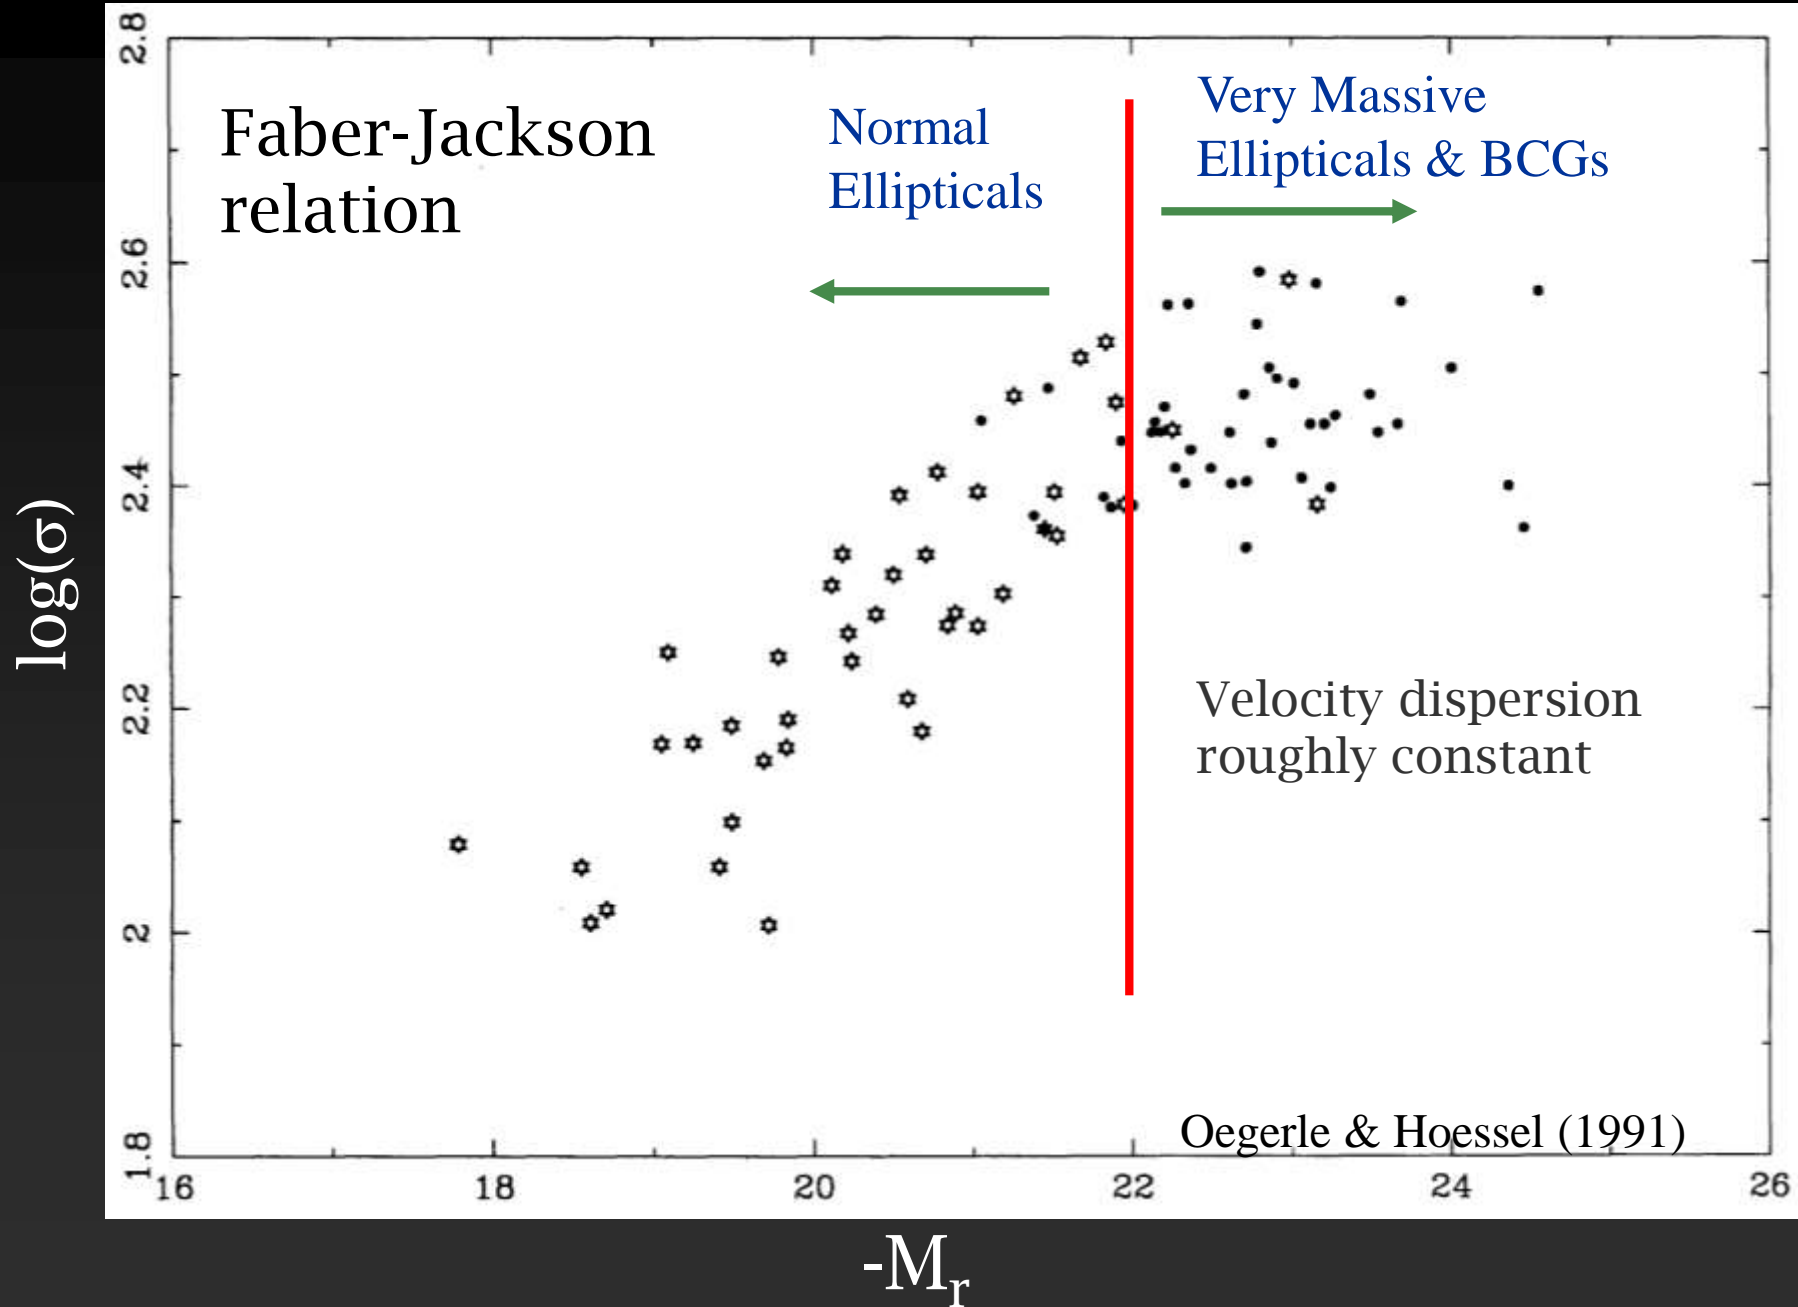

$$\beta > 4, \alpha > 0.6$$

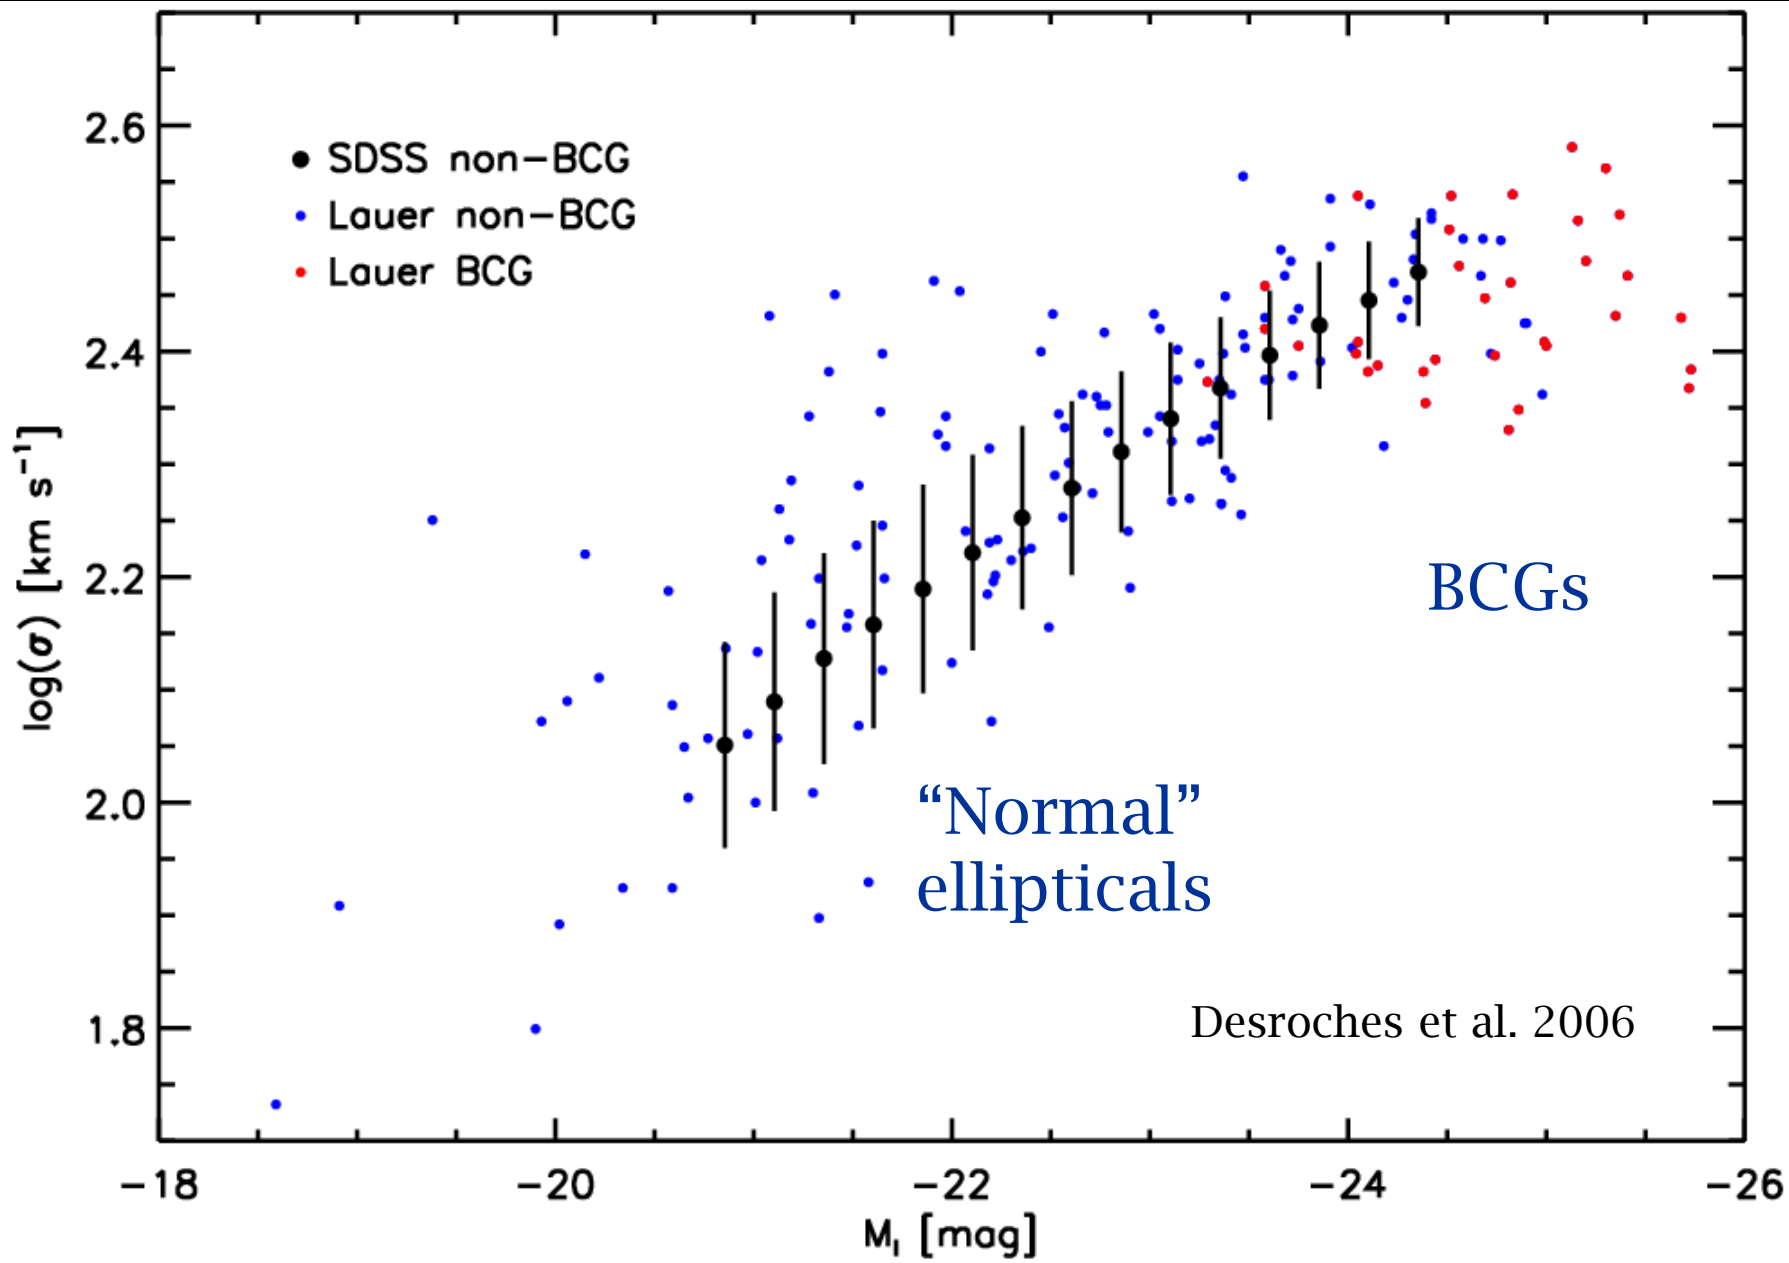

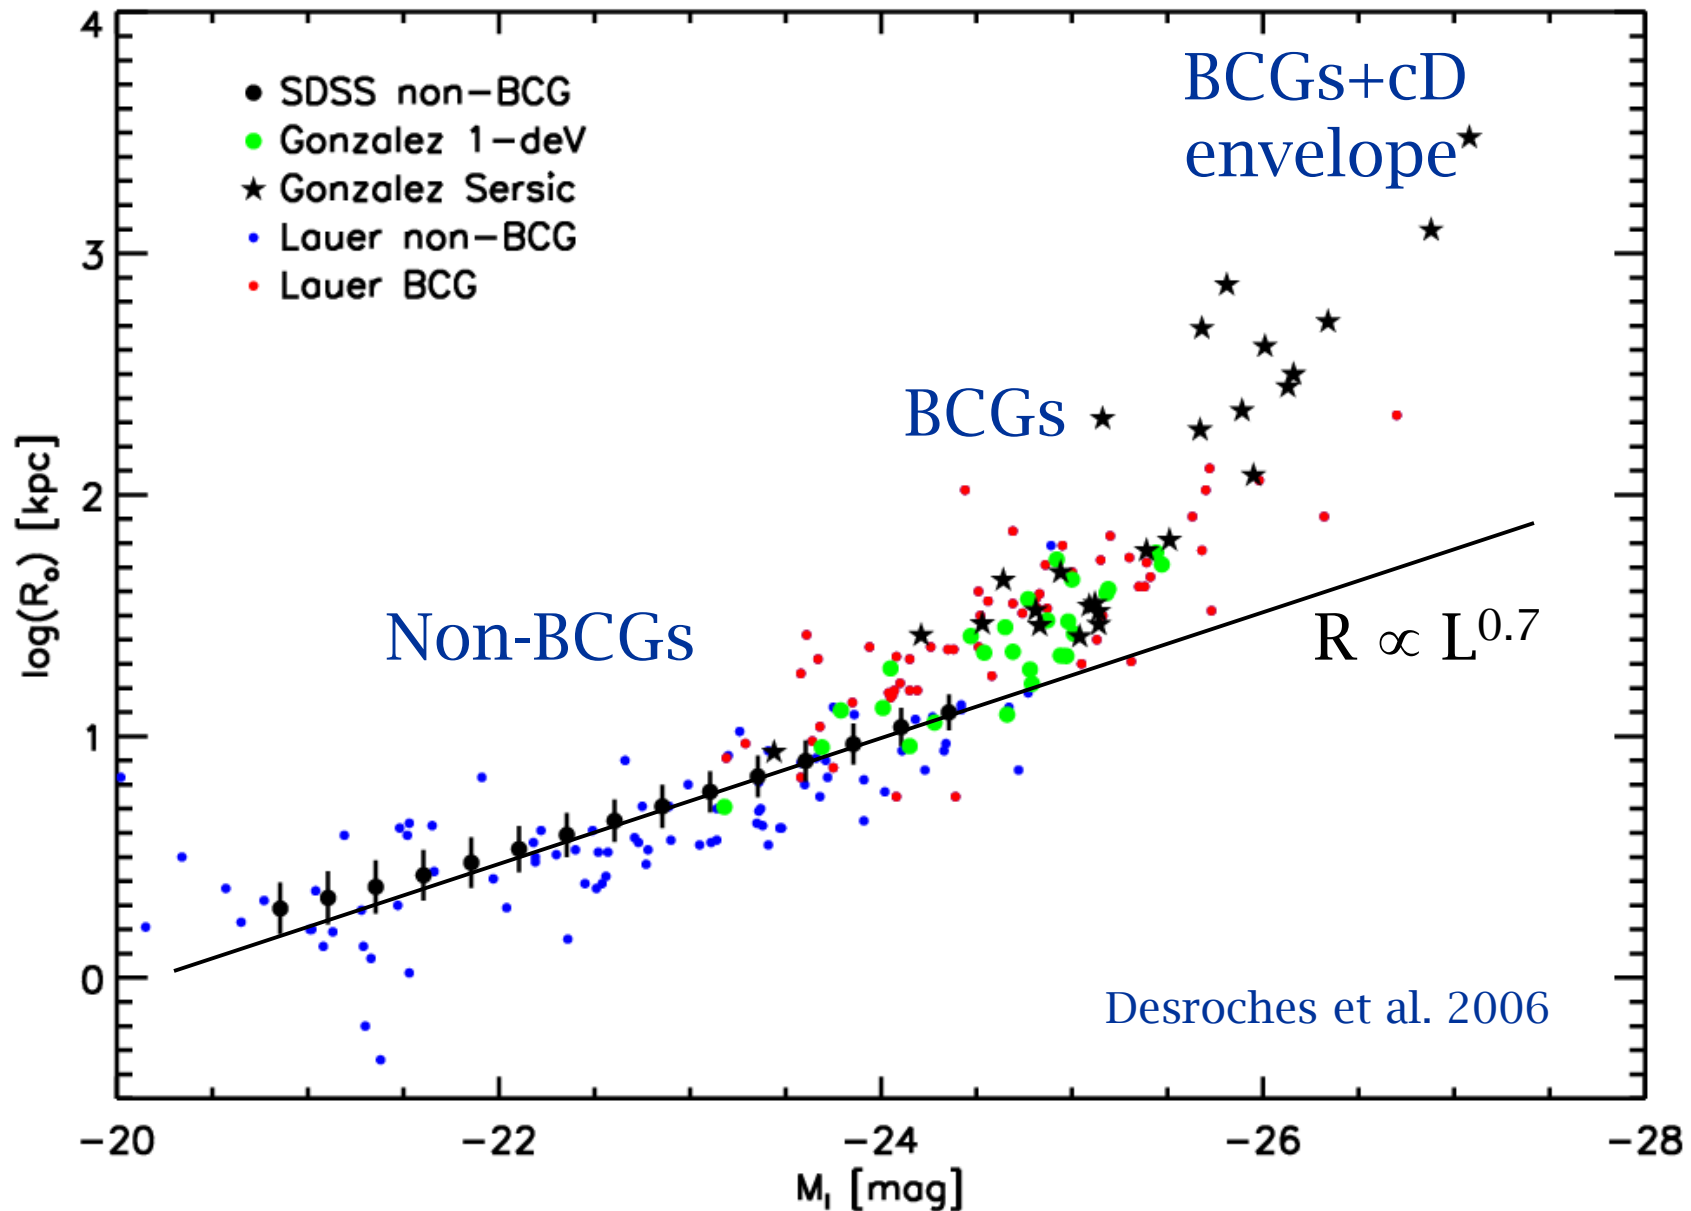

# Fundamental Plane

Oegerle & Hoessel (1991)

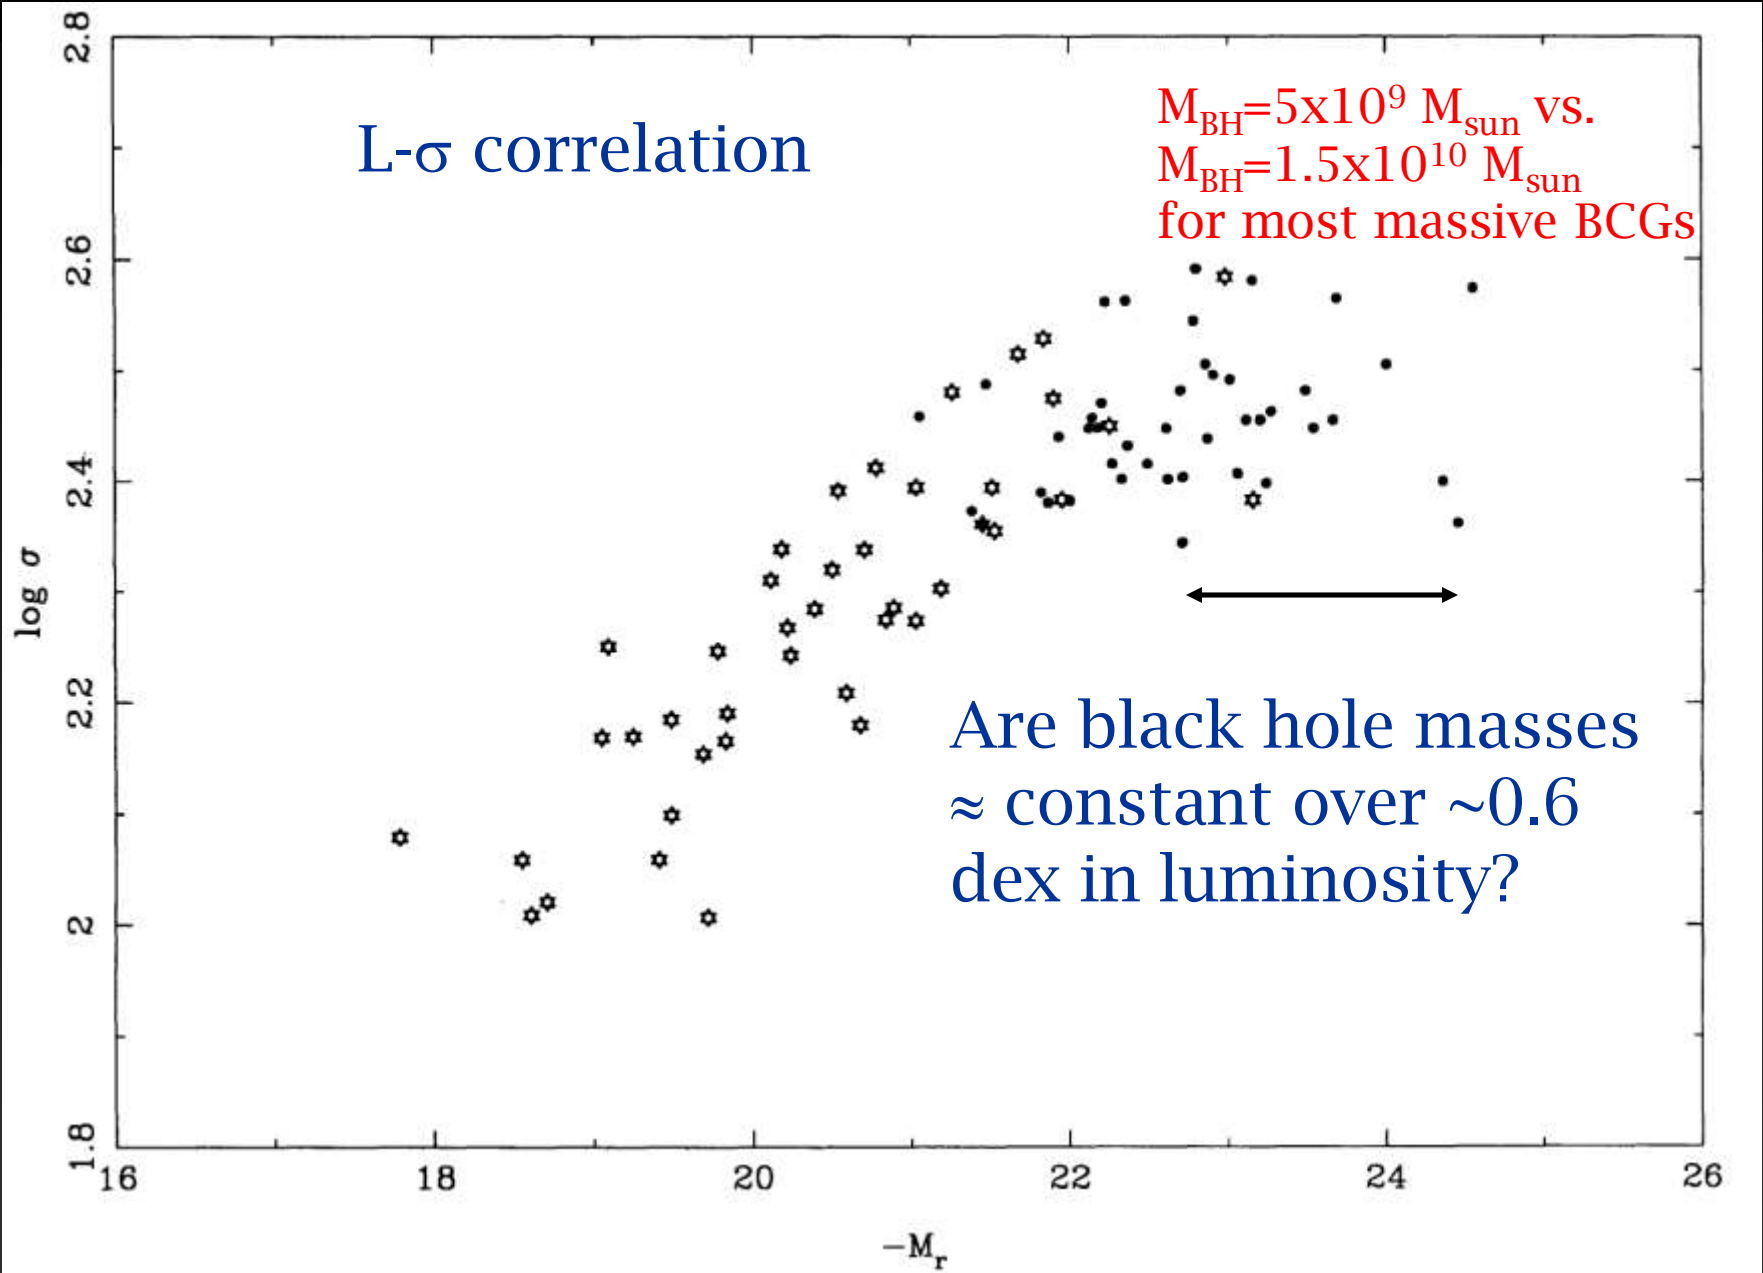

# What About Black Holes?

- Dry assembly of BCGs / massive ellipticals:  
BH growth comes from **mergers**

Dry merger predictions for BCGs:

- Black hole mass traces **galaxy stellar mass**:  $M_{\text{BH}} \propto M_{\text{gal}}$
- Different  $M_{\text{gal}}-\sigma$  relation:  $M_{\text{gal}} \propto \sigma^\beta$  with  $\beta > 4$

$\Rightarrow M_{\text{BH}}-\sigma^\beta$  relation changes to  $\beta > 4$

(see also Lauer et al. 2006, Bernardi et al. 2006)

# Conclusions

- The fundamental plane is preserved by dry merging under a variety of orbital configurations and mass ratios
- The FP projections *do show dependence* on merger orbit, a result of dynamical friction energy loss
- Radial merging along filaments is a well-motivated mechanism for producing BCGs; should lead to *BCGs following different FP projections* from normal ellipticals (now observed)
- Change in L- $\sigma$  relation for massive galaxies means using standard black hole mass predictor ( $M_{\text{BH}} \propto \sigma^4$ ) *may underestimate black hole masses*: BCGs could host black holes of  $>10^{10} M_{\text{sun}}$

# Fundamental Plane Projections

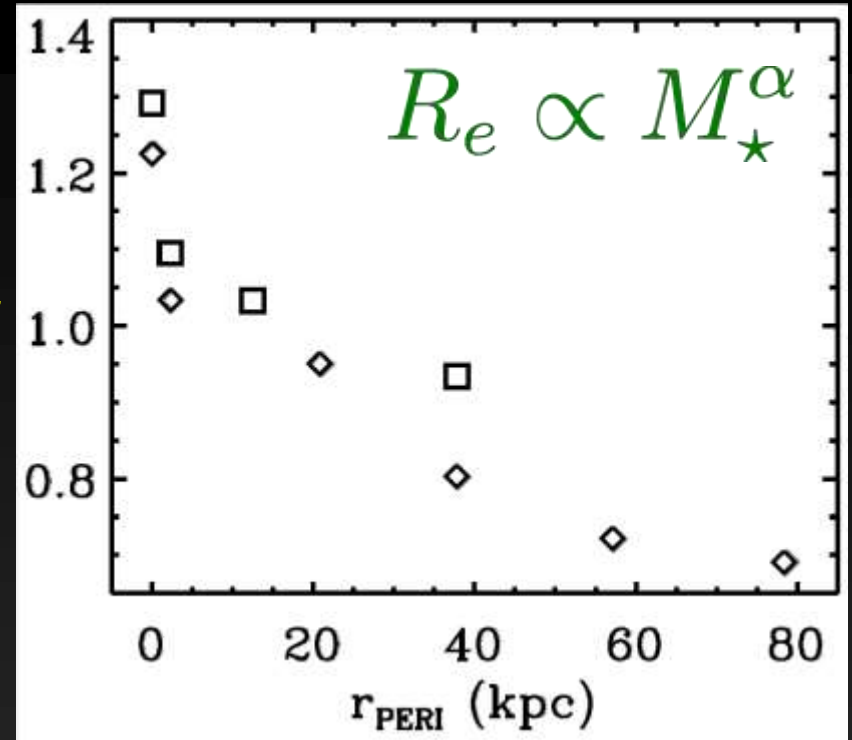

MBK, Ma, & Quataert (MNRAS, 2006)

$\beta$

Angular momentum

$\alpha$

observed:

$$M \propto \sigma^4$$

$$R_e \propto L^{0.6-0.7}$$

$\Rightarrow$  scaling relations depend on energy and angular momentum of orbit

# Predictions

- Dry mergers will preserve the fundamental plane
- If the mergers are on typical orbits (significant angular momentum), they will also preserve projections of the FP
- More radial mergers will lead to deviations in projections of the FP

*Q: when (if ever) are low angular momentum mergers expected?*

← Fundamental Plane

R vs. L →

Bernardi et al. 2006; also Lauer et al. 2006

# Deviations also seen for other massive ellipticals (Desroches, Quataert, Ma, and West 2006)

# Constraints on Galaxy Assembly

**fundamental plane** connects ellipticals' half-light radii ( $R_e$ ), luminosities ( $L$ ), and velocity dispersions ( $\sigma$ ):

(Djorgovski & Davis 1987, Dressler et al. 1987)

$$R_e \propto \sigma^{1.53 \pm 0.08} I_e^{-0.79 \pm 0.03} \Rightarrow R_e \propto \sigma^{-3} L^{3/2}$$

Pahre et al. 1998 (K-band)

**virial theorem** connects  $R$ ,  $\sigma$ , and  $M$

$$R \propto \sigma^{-2} M \Rightarrow R \propto \sigma^{-2} (M/L) L$$

$\Rightarrow$  require  $(M/L) \propto L^{1/2} \sigma^{-1}$  or (tilt)

Locations in :  $L \propto \sigma^4$  (Faber-Jackson),  $R \propto L^{0.7}$

contain **more** information than plane itself

# Future Work

- Reproducing scaling relations is only one piece of the puzzle: need to understand if dry merging works in other ways too
- Need to embed merger simulations into cosmological environment: multiple mergers, realistic merging sequence
- Make predictions for black hole mass function and its evolution - implications for galaxy formation at higher redshifts?
- **Observations:** measure more black hole masses in **BIG** galaxies (using adaptive optics) to get better statistics

# Example: Virgo Cluster / M87

- Virgo / M87
  - $M_{\text{p}} \approx 6 \times 10^{11} M_{\text{sun}}$
  - $\sigma_{\text{M87}} \approx 340 \text{ km s}^{-1}$
  - $M_{\text{BH}} = 3.0 \times 10^9 M_{\text{sun}}$
- Massive clusters:
  - $M_{\text{p, BCG}} \approx 1-3 \times 10^{12} M_{\text{sun}}$  (or more?)
  - maximum  $\sigma \approx 400 \text{ km s}^{-1}$
  - gives:
    - $M_{\text{BH}} = 5.8 \times 10^9 M_{\text{sun}}$  (using  $M_{\text{BH}}-\sigma$ )
    - $M_{\text{BH}} = 2 \times 10^{10} M_{\text{sun}}$  (using  $M_{\text{BH}}-M_{\text{p}}$ )

Projections:

$$L \propto \sigma^4 \quad (\text{Faber-Jackson})$$

$$R \propto L^{0.7}$$

Projections carry **more** information than plane itself
